Introduction

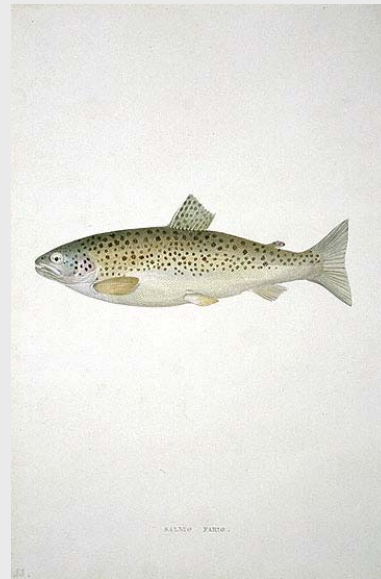

❑ Understanding the life-history and migration of brown trout is both

➤ A Biological Question

- Salmonid ecology

➤ A Management Question

- Protection of the fishery

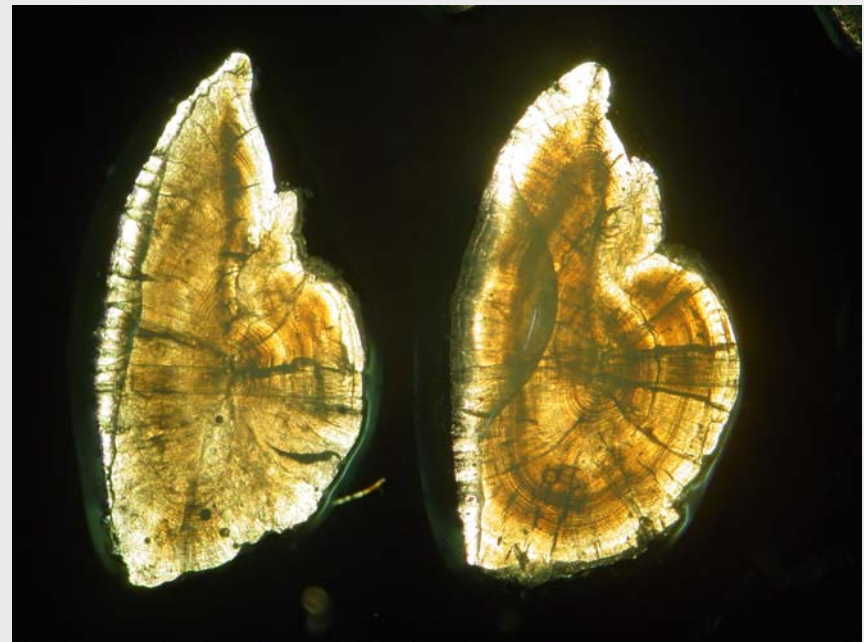

❑ Of particular Importance is an understanding of which tributaries within a catchment sustain the downstream population

The Otolith — “Black Box”

Firstly

Continuous growth

- Calcium Carbonate structure
- Varied growth rates, but constant deposition of new material

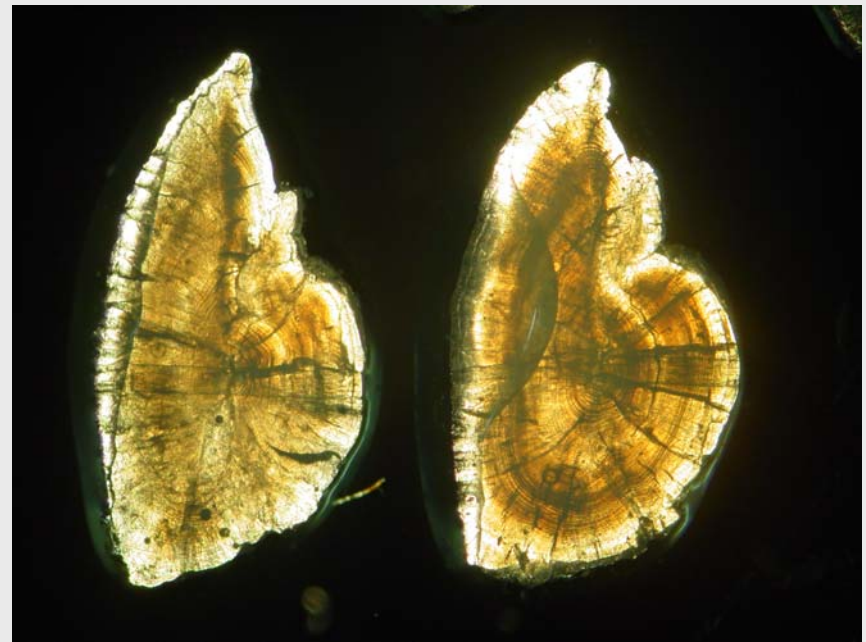

The Otolith — “Black Box”

Secondly

Trace element incorporation

- Elements substituted into the crystal lattice in place of calcium
- Elements vary between different environments
 - Geology
 - Land use

The Otolith — “Black Box”

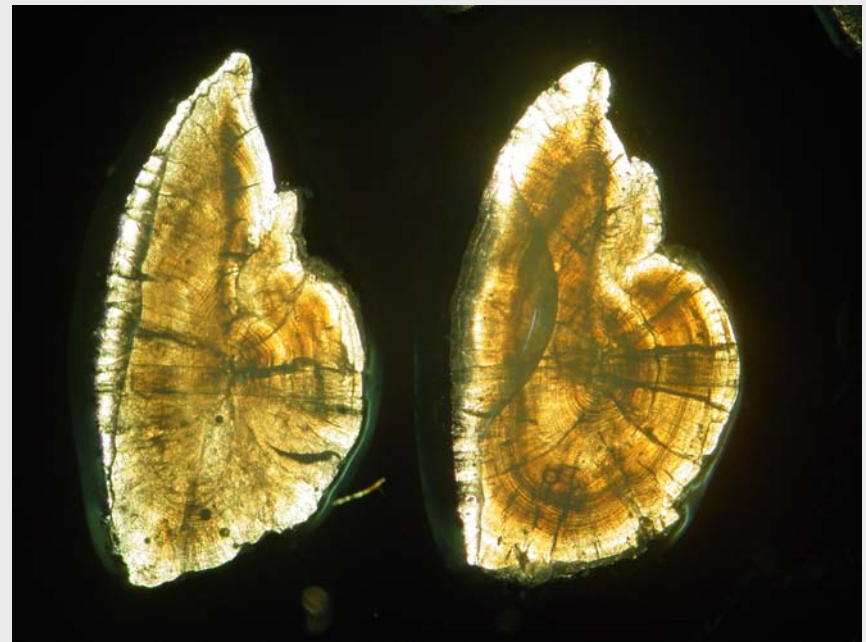

Thirdly

No metabolic re-distribution

- Elements remain trapped for the life of the fish.

So...

- Environmental fingerprint can be predicted over the entire life of the fish

Aims

Part 1

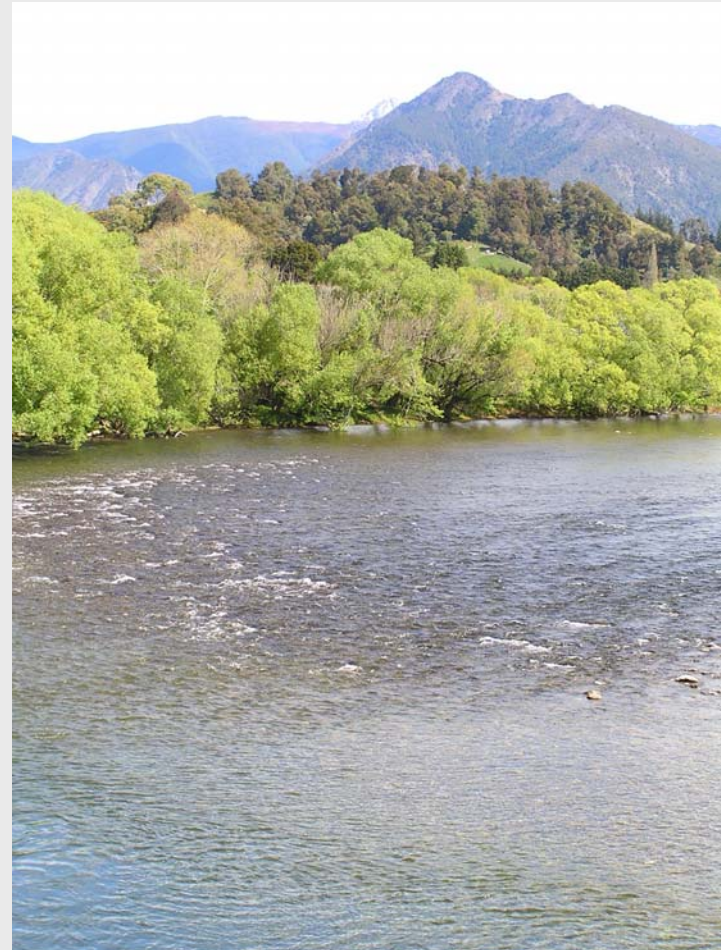

- Create an element map of the catchment by examining the otoliths of juvenile fish from a range of tributaries

Part 2

- Trace adult fish back to the tributaries to gain an understanding of recruitment importance

Motueka River

- Diverse Geology and land use.
 - Creates diverse element fingerprints
- Nationally renowned brown trout fishery.

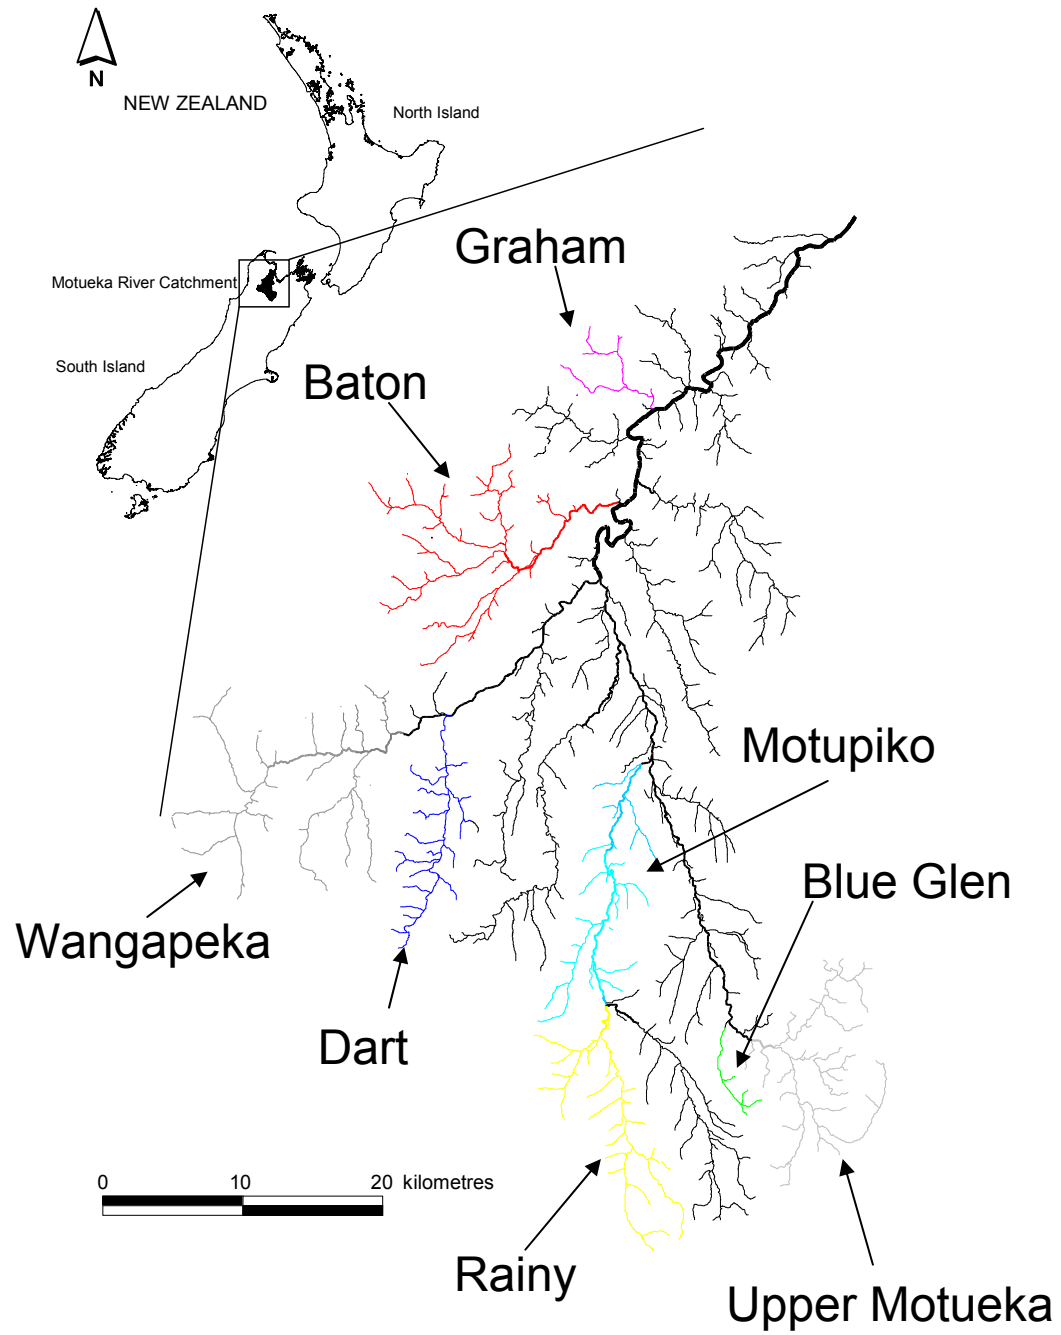

Part 1

Creation of the Element Map

Methods Overview

- Juvenile Fish collected from a range of tributaries
- Elemental signatures of otoliths analysed by ICPMS
- Signatures entered into a discriminant function analysis to classify the element signature of each stream.

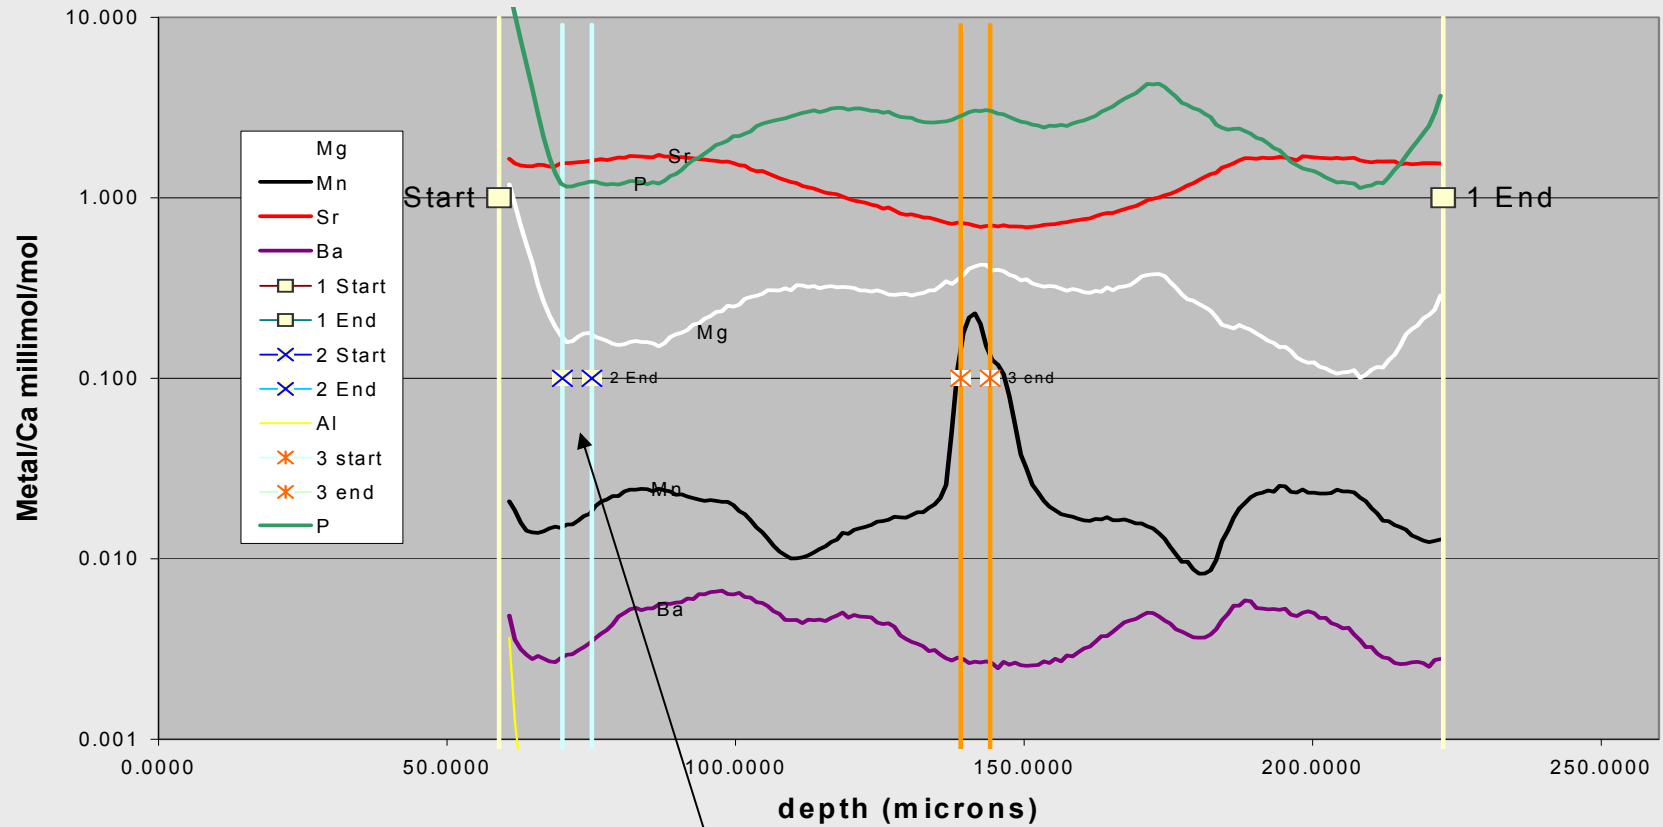

LA-ICPMS

(Laser Ablation Inductively Coupled Plasma Mass Spectrometry)

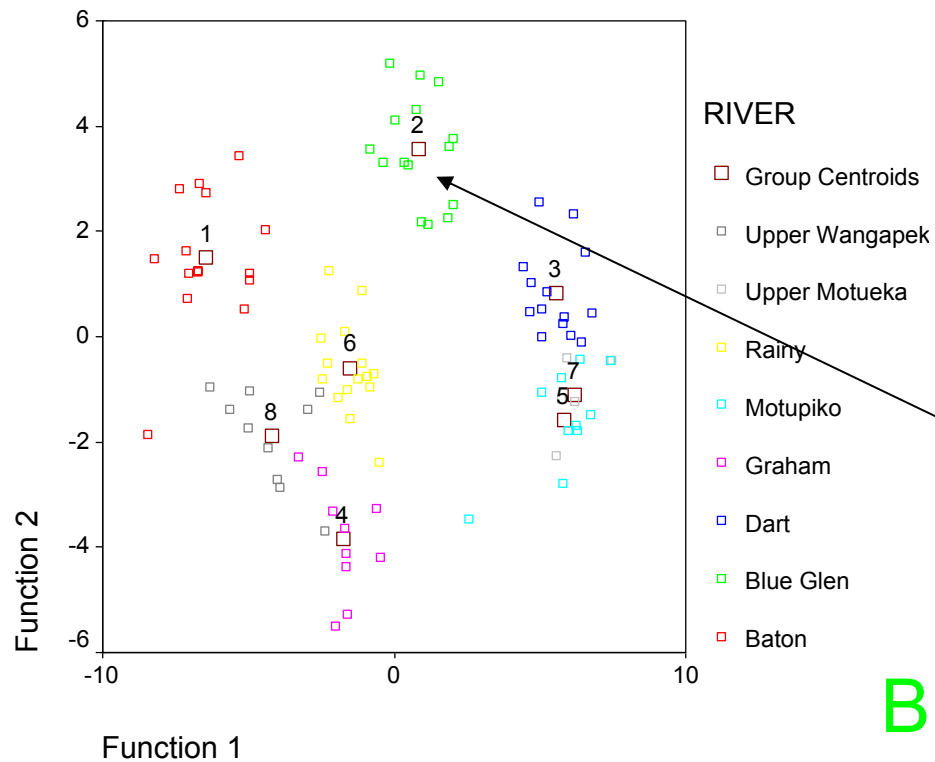

- Otolith is cleaned and placed in a sealed chamber.
- Laser beam is fired at the otolith .
- Otolith material is ablated and transferred into a mass spectrometer.
- Amount of each element determined by atomic mass .

Juvenile Profile

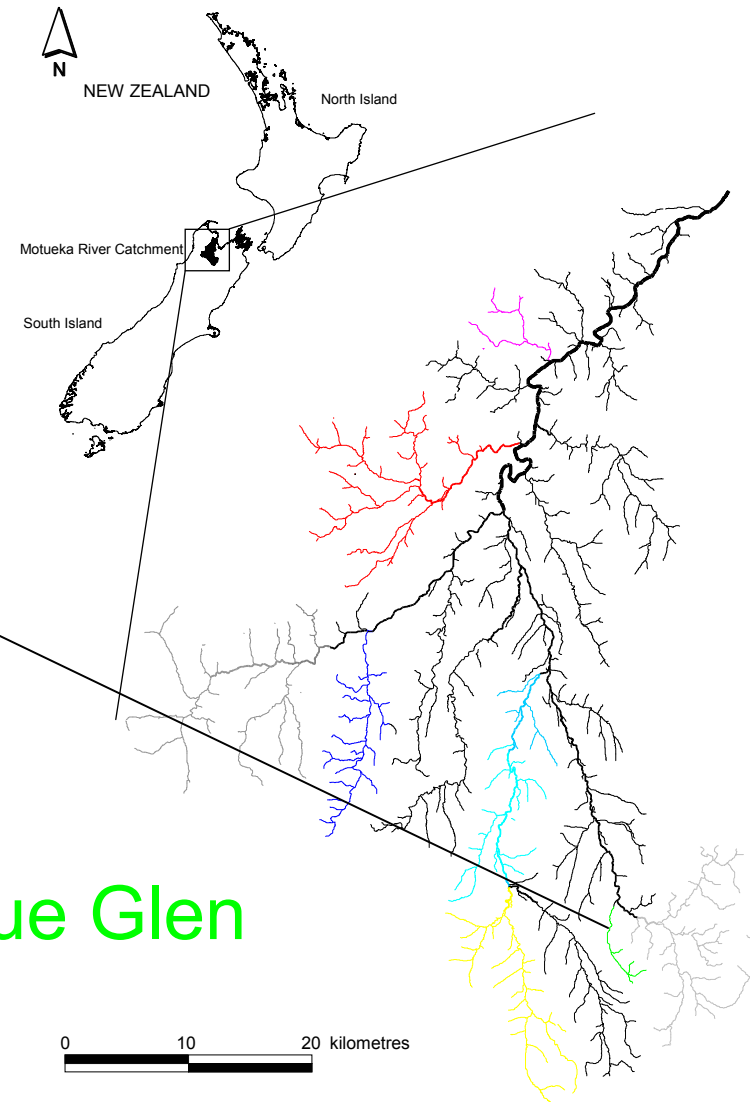

Edge Zone = Most recent otolith material = Tributary signature

Multi element fingerprint for each tributary

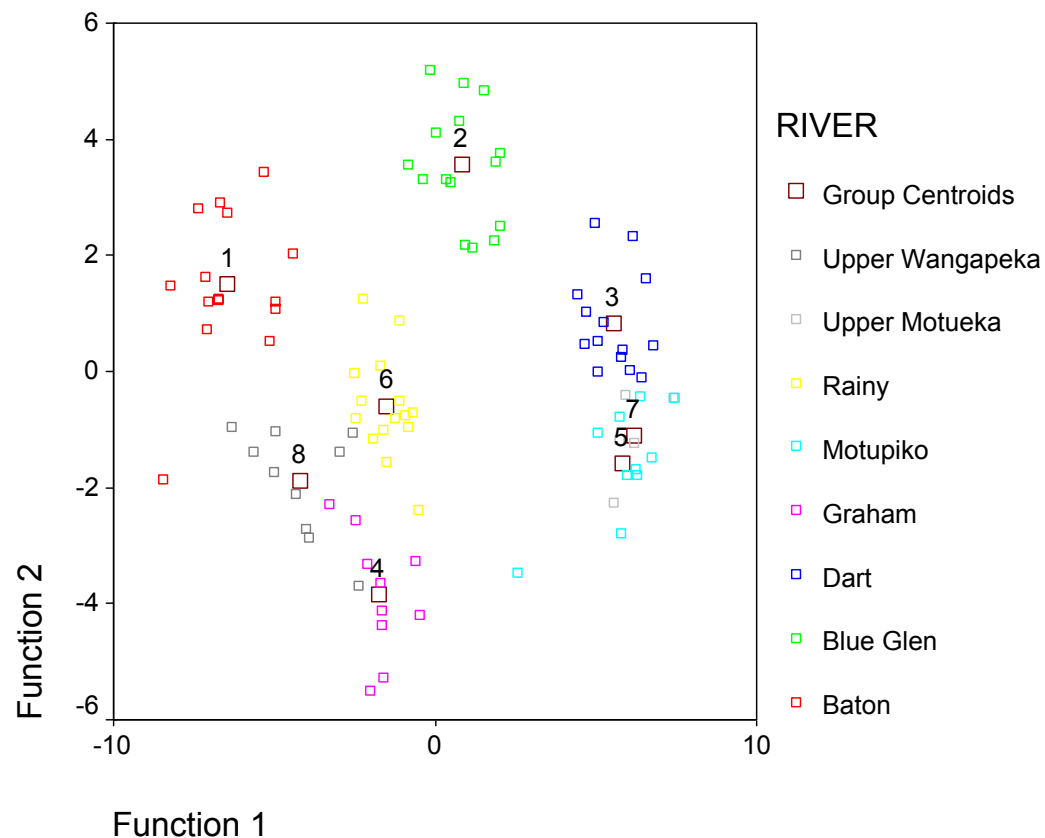

Elements used: Strontium, Barium, Manganese.

Classification

Overall 94.7% of the juvenile fish correctly classified to the stream they were caught

Tributary	% Classification
Overall	94.7
Baton	93
Blue Glen	100
Dart	100
Graham	100
Motupiko	100
Rainy	100
U. Motueka	100
U. Wangapeka	60

Part 2

Tracing back the adult fish

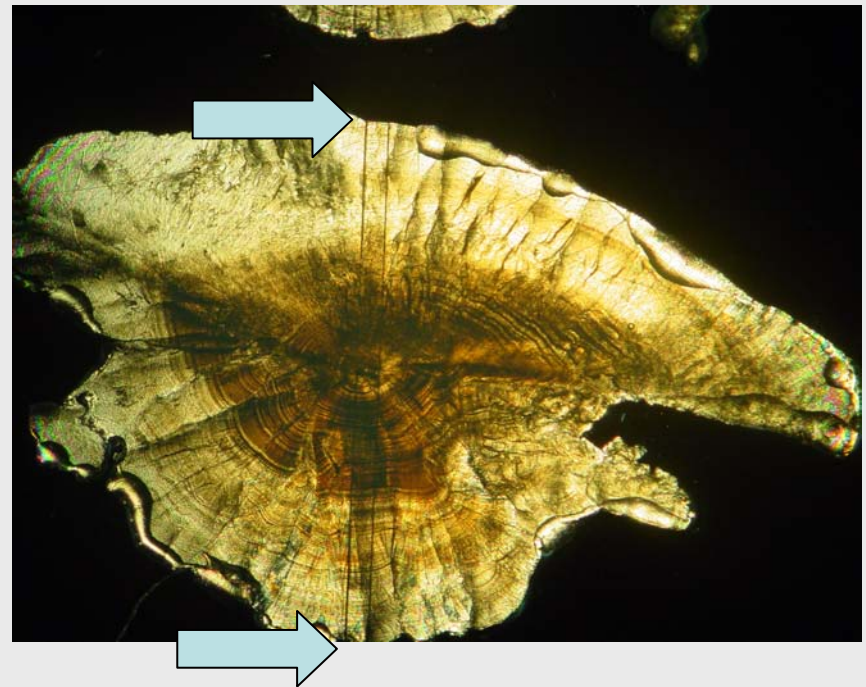

Methods Overview

- Adult fish collected from the main stem of the Motueka River
- Elemental signatures of otoliths analysed by ICPMS
- Adults entered into the juvenile analysis as unknowns to estimate for each a likely rearing tributary.

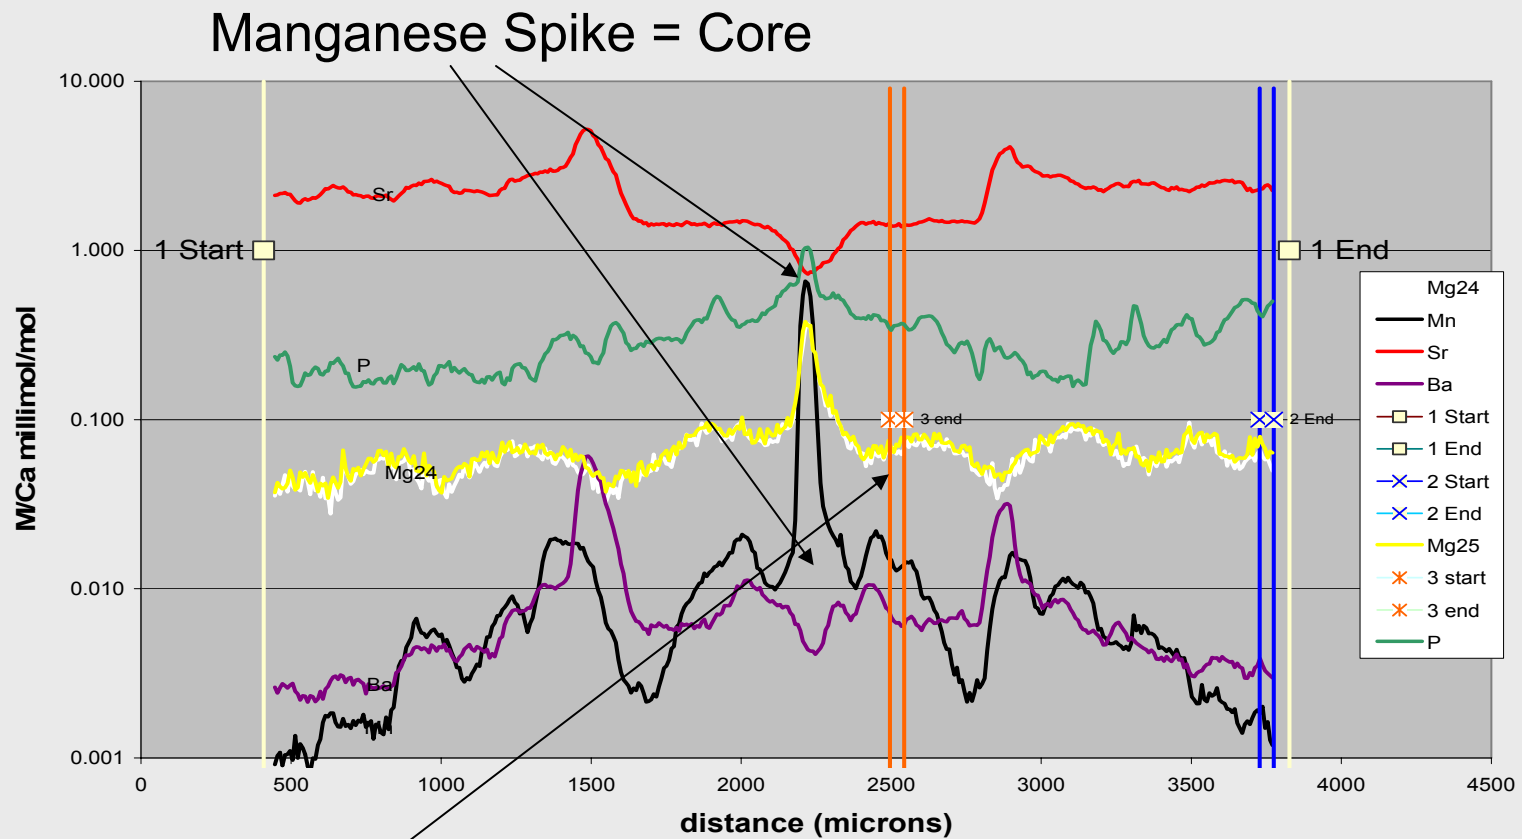

Adult Preparation

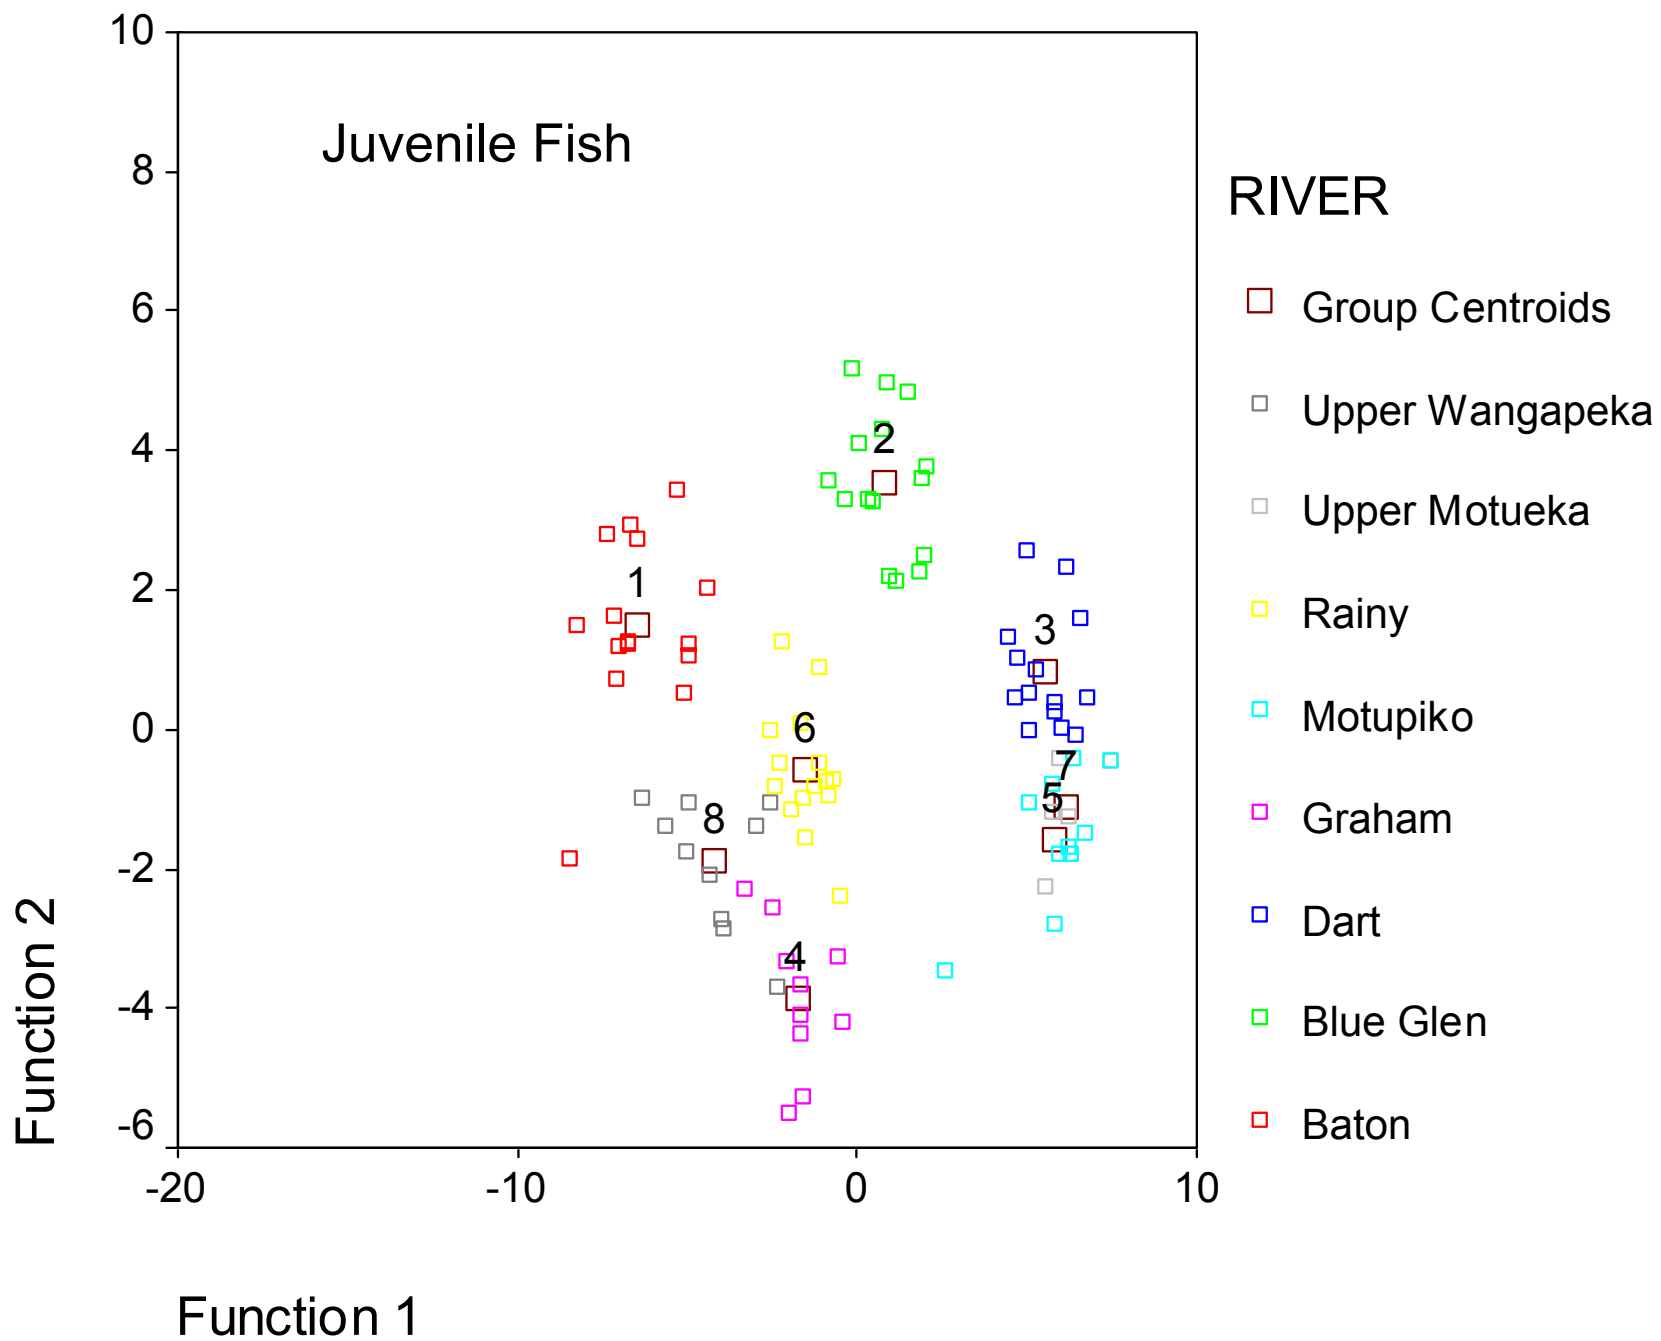

- Removed, cleaned and ground to a thin section
- Laser used to scan a transect from edge to edge through the core

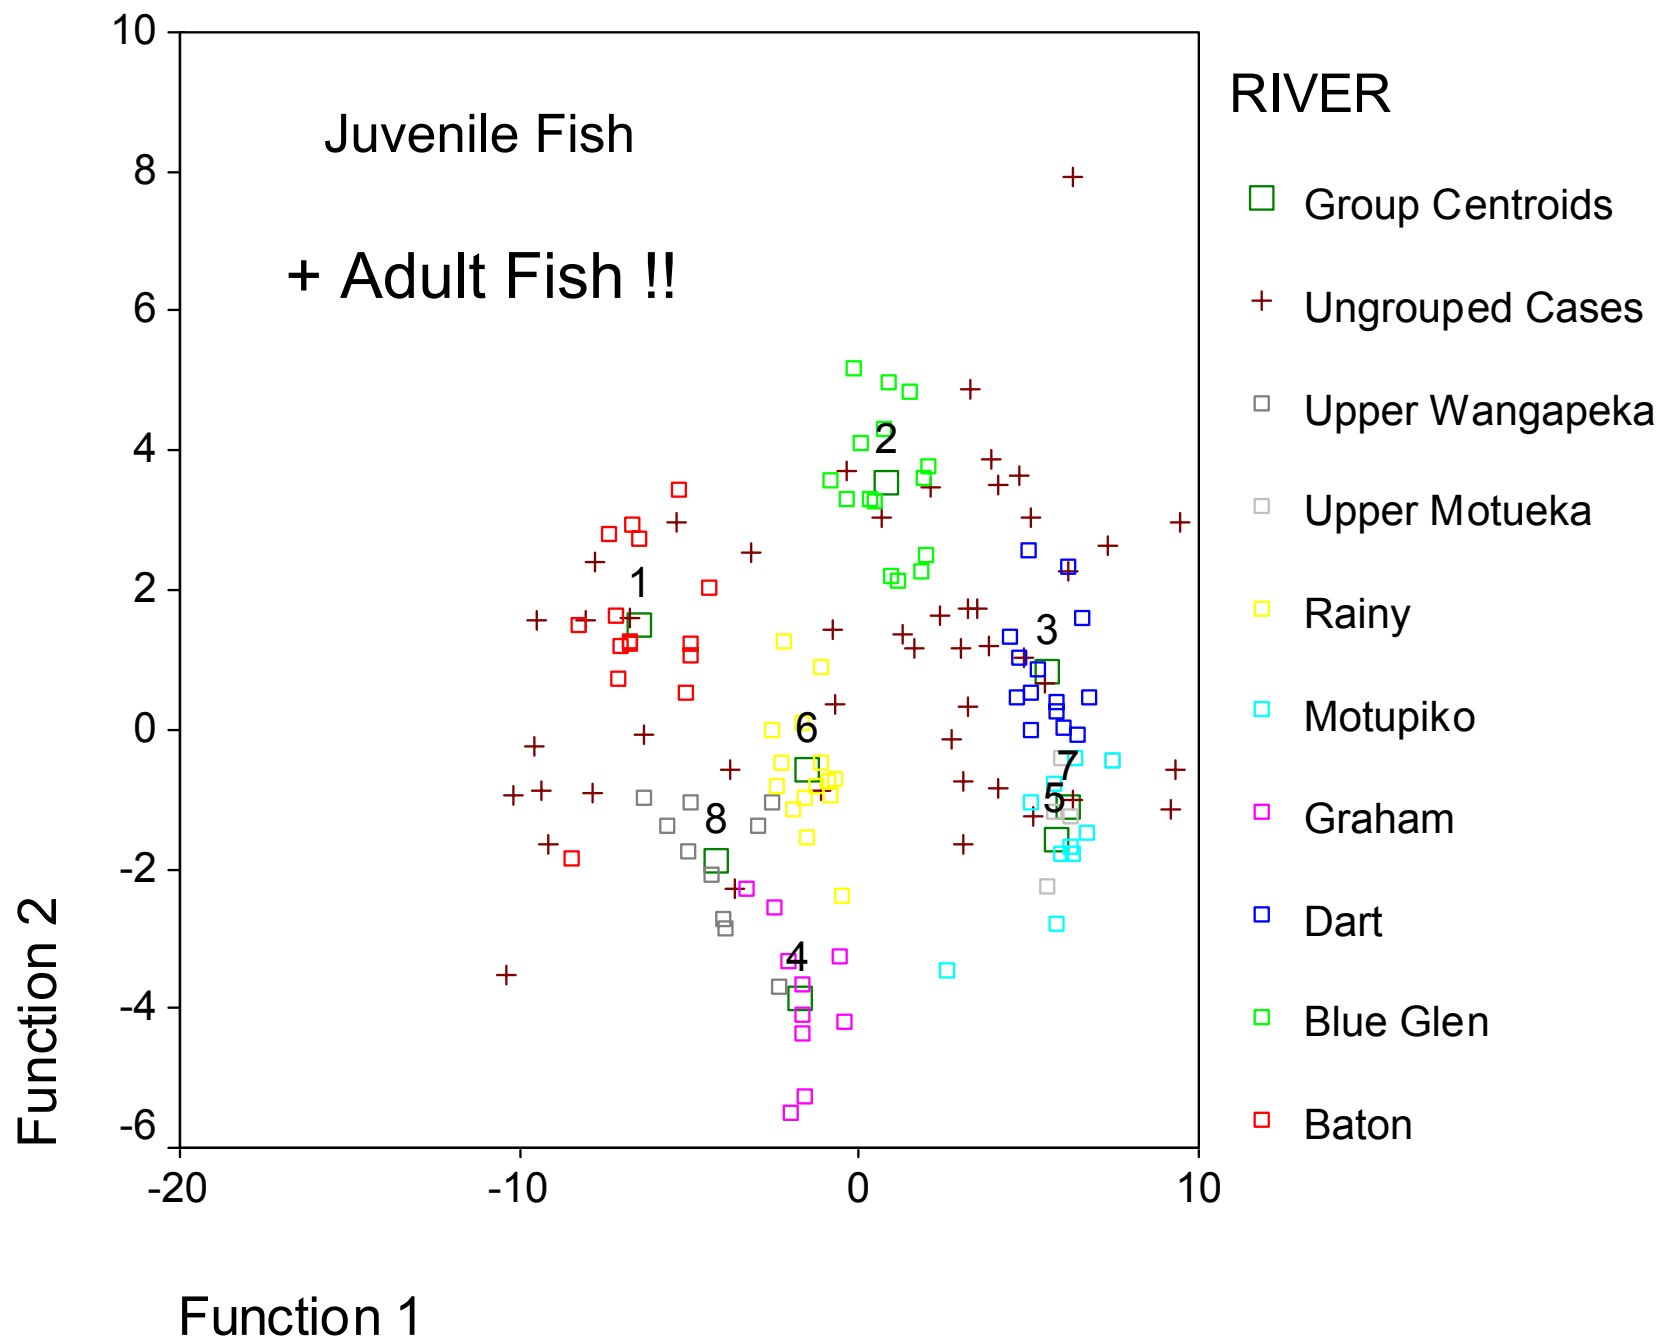

Adult Profile

Rearing Zone = 200microns from the core

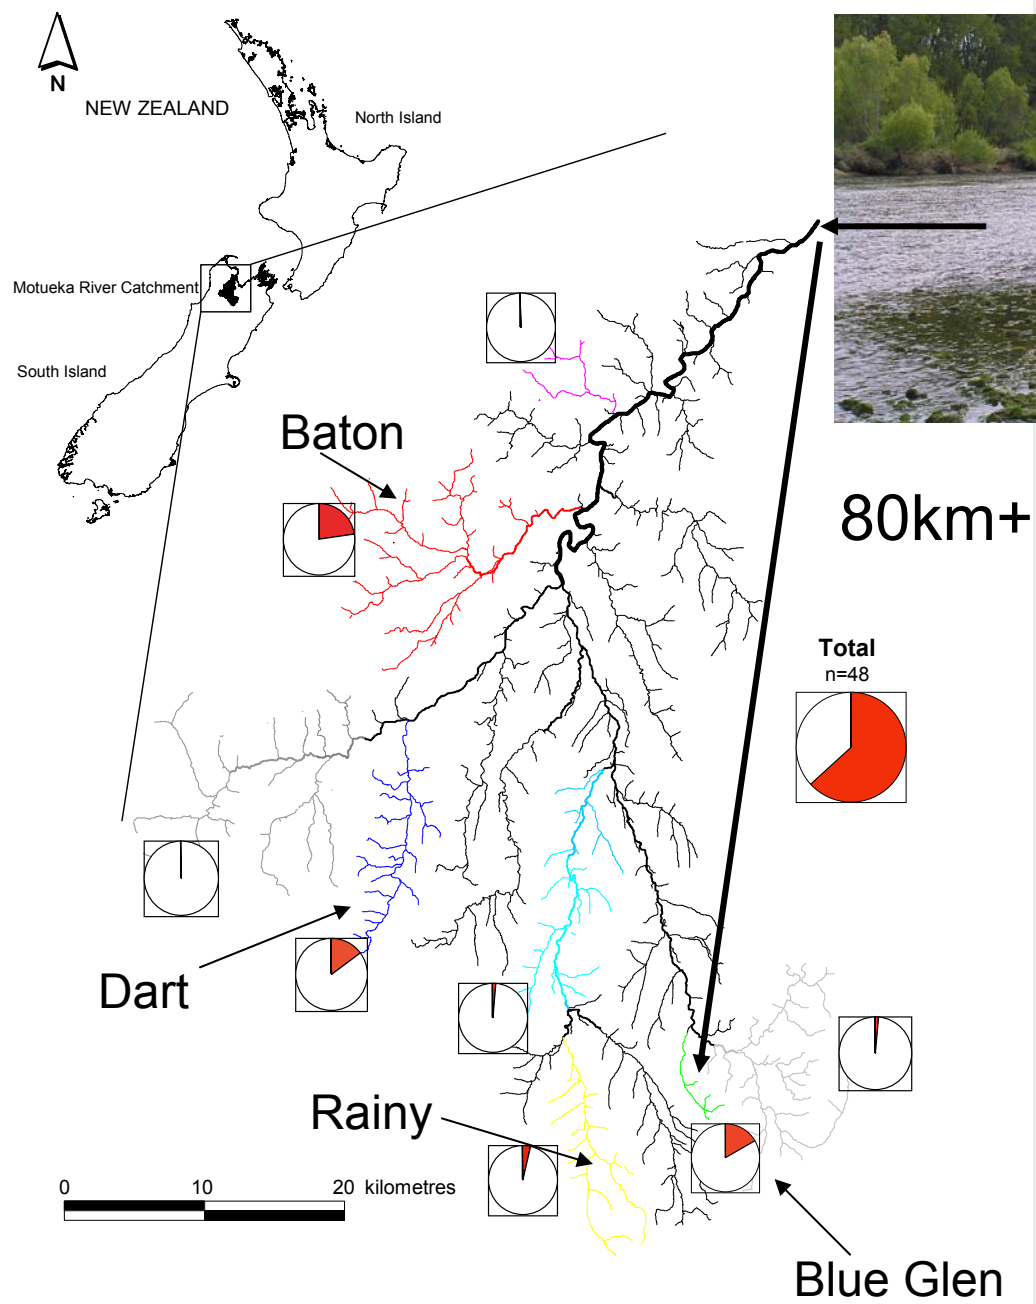

Adults entered into the analysis as unknowns

➤ This gave...

- The tributary each adult fish was most likely to have come from
- And a probability defining how well it matched

➤ To quantify recruitment adults matching a specific tributary with 95% confidence were examined

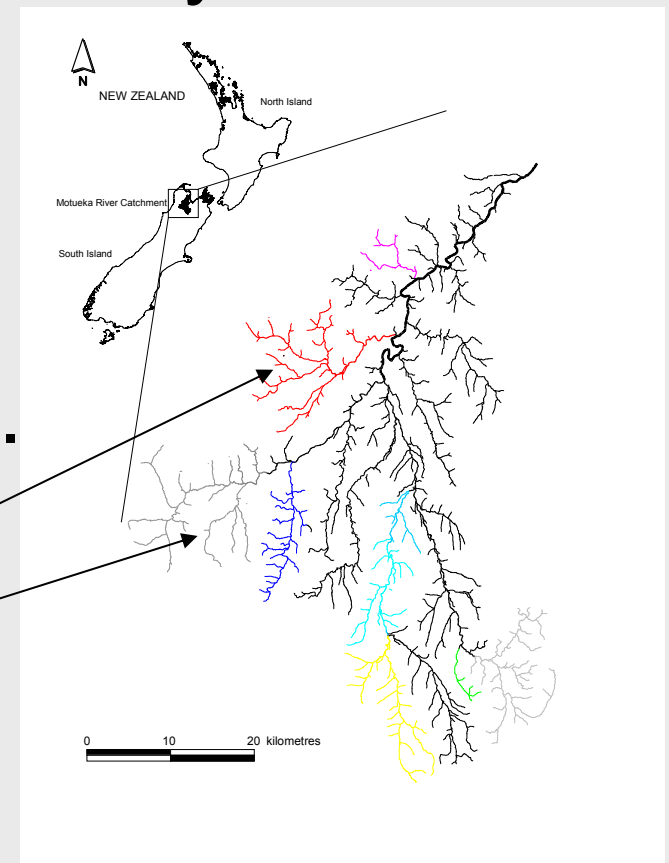

Conclusions — Motueka River

- Recruitment processes occurring at the catchment scale.
- Beginning to get an idea of important parts of the catchment sustaining the downstream fishery.
- Further investigation should clarify the pattern further.

Conclusions – Potential in the Method

- Differentiation within a completely freshwater catchment.
 - Classification of 94.7%
- Element map enhancement.
 - Strontium isotopes
 - Smaller streams
 - (Baton, Wangapeka)

The background of the slide is a close-up photograph of water with many small, overlapping ripples. The light reflects off the surface, creating a shimmering, textured effect with various shades of blue, green, and yellow.
